Supporting Information Methods S1: Species rate of budburst calculations

Due to the paucity of data for BBCH 7 in the PEP725 dataset, we were unable to use observations for both budburst and leafout to determine the durations of vegetative risk. Instead, we used data from a growth chamber experiment (Flynn & Wolkovich, 2018) to determine the average number of days between budburst and leafout for our study species. We took the mean number of days between budburst and leafout for the entire experiment, which was 12 days. We compared this number to a field observation study (Donnelly et al., 2017) that looked at the time between budburst and leafout across 10 species over 5 years. Finally, we assessed data that were provided by the USA National Phenology Network and the many participants who contribute to its Nature's Notebook program (USA-NPN,2019; www.usanpn.org/data/observational) for Aesculus flava (Sol.), Aesculus glabra (Willd.), Alnus incana (Moench.), Betula nigra (L.), Betula papyrifera (Marshall), Fagus grandifolia (Ehrh.), Fraxinus americana (L.), Fraxinus nigra (Marshall) and Quercus velutina (Lam.) and took the mean number of days between budburst and leafout. Across all three approaches, the average number of days between budburst and leafout was approximately 12 days. Thus, we expanded our rate of budburst through full leaf expansion by subtracting 12 days from the first leaf to find budburst and adding 12 days to the first leaf to find full leafout.

Again, due to a lack of BBCH 7 data, we were unable to determine species-specific averages of number of days between budburst and leafout. We used a similar approach as above by using data from the growth chamber experiment (Flynn & Wolkovich, 2018) but instead of finding whole experiment means we determined species-specific averages. We used the rate of budburst of Acer saccharum (Marshall) for Aesculus hippocastanum (Buerki et al., 2010), Alnus incana for Alnus glutinosa, Betula papyrifera for Betula pendula (Wang et al., 2016), Fagus grandifolia for Fagus sylvatica, Fraxinus nigra for Fraxinus excelsior and Quercus alba (L.) for Quercus robur (Hipp et al., 2018).

Supporting Information Methods S2: Spatial parameter

Spatial autocorrelation (SA) is a common issue in spatial ecology given that nearby spatial units tend to be more similar than units far apart, and thus, cannot be considered as independent units, which is a frequent assumption in statistical tests (Diniz-Filho *et al.*, 2003). If model residuals are spatially autocorrelated, and thus, non-independent then model coefficients and errors may be biased in a hard-to-predict way (Mauricio Bini *et al.*, 2009). On the contrary, if model residuals are not autocorrelated, then SA should not be of concern (Hawkins, 2012).

To control for spatial autocorrelation and to account for spatially structured processes independent from our environmental predictors of false springs, we generated an additional spatial predictor for the model. To avoid collinearity, we computed our spatial predictor from the residuals of a linear model of false springs as a function (Equation S1) of all other factors that are also spatially structured (e.g. spring temperature, altitude, distance to the coast), following the logic of spatial filter modelling (Diniz-Filho & Bini, 2005). The calculation of the spatial predictor followed the next steps: (a) we fit a linear model of false spring versus environmental factors, (b) we extracted the residuals of the regression Equation S1, which represent the portion of the variation in the number of false springs that is independent from the predictors in the model and (c) we utilized the residuals as our y_i values in a selection of spatial eigenvectors to retain only the minimal subset of spatial eigenvectors that are able to remove SA from model residuals. Specifically, we selected eigenvectors following the the minimization of Moran's I of the residuals (MIR) approach (Griffith & Peres-Neto, 2006; Diniz-Filho et al., 2012; Bauman et al., 2017). (d) Next, we fit a linear model between the residuals of Equation S1 and the subset of selected eigenvectors. And, finally, (e) we took the fitted values from this regression as our spatial predictor in our final model (see equation from main text, Equation 1), which can be interpreted as a latent variable summarizing the spatial structure in false springs that is unaccounted for by the rest of the environmental factors in our model (Morales-Castilla et al., 2012).

$$y_{i} = \alpha_{[i]} + \beta_{NAO_{[i]}} + \beta_{MST_{[i]}} + \beta_{Elevation_{[i]}} + \beta_{DistanceCoast_{[i]}}$$

$$+ \beta_{ClimateChange_{[i]}} + \beta_{NAO \times Species_{[i]}} + \beta_{MST \times Species_{[i]}} + \beta_{Elevation \times Species_{[i]}}$$

$$+ \beta_{DistanceCoast \times Species_{[i]}} + \beta_{ClimateChange \times Species_{[i]}}$$

$$+ \beta_{NAO \times ClimateChange_{[i]}} + \beta_{MST \times ClimateChange_{[i]}} + \beta_{Elevation \times ClimateChange_{[i]}}$$

$$+ \beta_{DistanceCoast \times ClimateChange_{[i]}} + \sigma_{[i]}$$
(S1)

Figure S1: Effects of species, climatic and geographical predictors on false spring risk with different rates of leafout for each species. More positive values indicate an increased probability of a false spring whereas more negative values suggest a lower probability of a false spring. Dots and lines show means and 98% uncertainty intervals. See Table S7 for full model output.

Figure S2: Effects of species, climatic and geographical predictors on false spring risk with a lower temperature threshold (-5°C) for defining a false spring. More positive values indicate an increased probability of a false spring whereas more negative values suggest a lower probability of a false spring. Dots and lines show means and 98% uncertainty intervals. See Table S8 for full model output.

9

Table S8: Summary of Bernoulli model of false spring risk with a lower temperature threshold $(-5^{\circ}\mathrm{C})$ for defining a false spring.

Intercept	(-5 C) for defining a raise spring.	mean	2%	10%	25%	75%	90%	98%

Figure S3: Effects of species, climatic and geographical predictors on false spring risk with a lower temperature threshold (-5°C) for early-leafout species (i.e., $Aesculus\ hippocastanum$, $Alnus\ glutinosa$ and $Betula\ pendula$) and a higher temperature threshold (-2.2°C) for lateleafout species (i.e., $Fagus\ sylvatica$, $Fraxinus\ excelsior$ and $Quercus\ robur$). More positive values indicate an increased probability of a false spring whereas more negative values suggest a lower probability of a false spring. Dots and lines show means and 98% uncertainty intervals. See Table S9 for full model output.

11

Table S9: Summary of Bernoulli model of false spring risk with varying temperature thresholds for early- versus later-leafout species.

for earry- versus later-leafout species.	mean	2%	10%	25%	75%	90%	98%

Figure S4: Average predictive comparisons for all climate change interactions with each of the main effects (i.e., mean spring temperature (\mathbf{a}) , distance from the coast (\mathbf{b}) , elevation (\mathbf{c}) , and NAO index (\mathbf{d})) for all species. Shading around the lines represent the 98% uncertainty intervals.

13

Figure S5: Species-level under the varying rates of leafout model across geographic and spatial predictors (i.e., mean spring temperature (\mathbf{a}) , distance from the coast (\mathbf{b}) , elevation (\mathbf{c}) , NAO index (\mathbf{d})) and recent climate change (\mathbf{e})). Lines and shading are the mean and 98% uncertainty intervals for each species. To show results on the original scale of the data we converted model output. See Table S6 for full model output.

Figure S6: Species-level variation with a lower temperature threshold (-5°C) model across geographic and spatial predictors (i.e., mean spring temperature (a), distance from the coast (b), elevation (c), NAO index (d)) and recent climate change (e)). Lines and shading are the mean and 98% uncertainty intervals for each species. To show results on the original scale of the data we converted model output. See Table S6 for full model output.

Figure S7: Species-level variation under the varying temperature thresholds model across geographic and spatial predictors (i.e., mean spring temperature (a), distance from the coast (b), elevation (c), NAO index (d)) and recent climate change (e)). Lines and shading are the mean and 98% uncertainty intervals for each species. To show results on the original scale of the data we converted model output. See Table S6 for full model output.
